A. NEW RENAULT ESPACE – LCA RESULTS

This part presents the results of the life cycle assessment of the new Renault ESPACE. It is a comparative LCA study and compares the new Renault ESPACE with the previous one launched in 2002.

I GOAL AND SCOPE OF THE ESPACE STUDY

For all Renault studies, the goal and scope and the global guidelines of the LCA analysis are the same and are described precisely in the methodological part of this report (from page 17, part B).

Functional unit and vehicles assessed

The functional unit for this study is the same as for other Renault studies. It is defined as the transportation of persons in a vehicle, for a total distance of 150 000 km, during 10 years, in compliance with type approval regulation over New European Driving Cycle. It is described precisely in the methodological part (page 18).

The two ESPACE vehicles assessed have standard equipment and similar characteristics that are described in the following table:

		ESPACE 4	ESPACE 5
General description	Constructor	RENAULT	RENAULT
	Denomination	Espace 4	Espace 5
	Production Start	02 – 2002	05-2015
	Category	VP – M1	VP – M1
	Body	H segment	H segment
Mechanical specification	Fuel	diesel	diesel
	Engine	2,0 L DCI (M9R)	1,6 DCI (R9M)
	Gearbox	BVM	BVA
	Max speed	184	202
	Emission standard for type approval (70/220/CEE)	EURO 5b	EURO 6
Dimension	Consumption (NEDC)	6,5 L/100km	4,7 L/100km
	Length	4856	4857
	Width	1894	1888
Emissions	Height	1746	1675
	CO2 (NEDC)	170 g/km	123 g/km
	CO (NEDC)	NC	287,7 mg/km
	HC (NEDC)	NC	36,2 mg/km
	NOx (NEDC)	NC	50,6 mg/km

Table 1 : Characteristics of the two vehicles compared: ESPACE 4 & ESPACE 5

For information, the emission limits according EURO 5a and EURO 6 (category M1: passengers vehicles <2500kg) for particular vehicles equipped with DIESEL engines are given in the following table:

	EURO 5a	EURO 6
CO (g/km)	0,500	0,500
HC (g/km)	0,100	0,100
NMHC (g/km)	0,230	0,170
NOx (g/km)	0,180	0,080
Part. Mass (mg/km)	5	5
Part. Number (#/km)	6x10 ¹¹	6x10 ¹¹

Table 2 : Emission limits according to EURO 5a and EURO 6 regulations

All details about emissions regulations are available in appendix VI.3.

II LIFE CYCLE INVENTORY

II.1 MATERIAL COMPOSITION

The following table shows the different materials composition of the 2 compared Espace:

	ESPACE 4	ESPACE 5
<i>Material categories</i>	<i>Total mass (kg)</i>	<i>Total mass (kg)</i>
1 - Metals	1360,6	1103,1
2 - Polymers	278,7	321,8
3 - Elastomers	68,1	73,3
4 – Glass and ceramic	45,2	53,4
5 - Fluids	34,6	12,8
6 – Organic material	2,7	11,0
7 - Others	18,8	4,2
TOTAL	1808,7	1579,6

Table 3 : Material description for ESPACE 4 & ESPACE 5

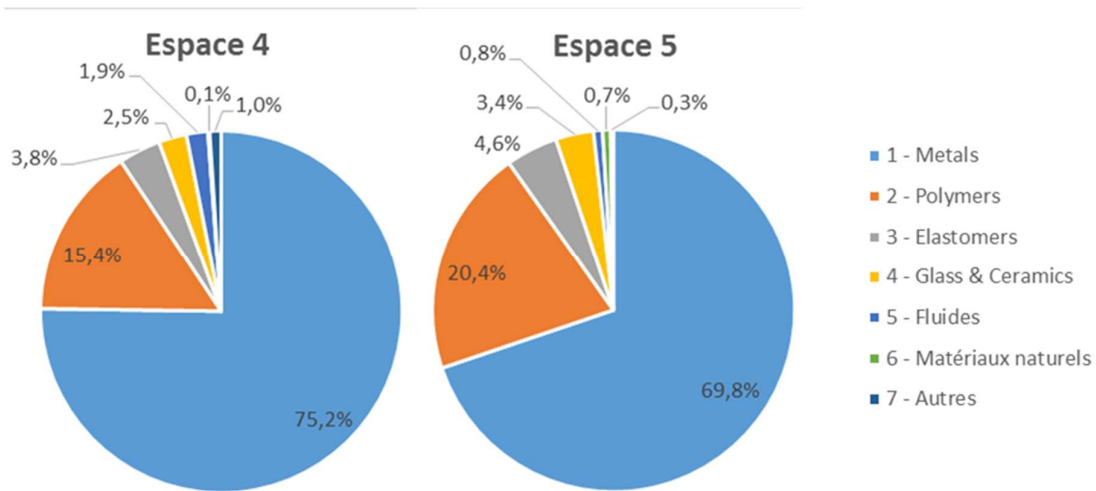

Figure 1 : Material distribution of ESPACE 4 & ESPACE 5

As described in the graphs, the distribution of the materials is quite different between Espace 4 and Espace 5.

There is a significant increase of the rate of plastics from 15% to 20%, which can be explained by the fact that parts have changed from metal to plastics in Espace 5 in order to reduce the weight of the car (tailgate for example).

Concerning the difference of 1% on the Glass category, it could be explained by the increase of screen surface and the use of reinforced glass.

II.2 PLANTS AND LOGISTICS

Espace 4 & Espace 5 are not assembled in the same factory, but the two plants are spaced by around 300 kilometers.

Table 4 shows also where engine and gearbox for both Espace are manufactured.

	Espace 4	Espace 5
Vehicle assembly factory	Sandouville (France)	Douai (France)
Engine factory	Cléon (France)	Cléon (France)
Gearbox factory	AJ0 (Angleterre)	DW6 (Autriche)

Table 4 : Production plants localization

The emissions and consumptions related to the vehicle assembly, engine and gearbox are taken into account.

Logistic is also estimated according to those data.

III RESULTS OF THE LIFE CYCLE IMPACT ASSESSMENT

III.1 NEW SPACE

Following Figure 2 presents the distribution of selected impacts all along the life cycle. Concerning the recycling phase, it is modelled according to reference scenario (see chapter III.6, p28).

Concerning the presentation of the results:

- Vehicle production includes raw material extraction and manufacturing, the production of parts and the assembly of the vehicle. It also includes logistics from first rank supplier to factory and to final customer.
- The use phase includes the production of fuel and the use of the vehicle all along its life cycle (as defined in the functional unit). It also includes the maintenance during the life cycle
- The end of life includes the different processes to dismantle and shred the end of life vehicle, also the recycling processes of the different specific parts of the car.

Associated data is gathered in Table 5.

Figure 2 : Repartition of environmental impact of ESPACE 5 along its life cycle

	QUANTITY	PART IN LIFE CYCLE
ADP fossil: Abiotic depletion Potential (fossil) [MJ]		
Vehicle Production	92303,30	23,55%
Use Phase	297227,34	75,84%
End of life	2387,30	0,61%
AP: Acidification Potential [kg SO2-Equiv.]		
Vehicle Production	31,14	49,58%
Use Phase	28,90	46,01%
End of life	2,77	4,41%
GWP: Global Warming Potential 100 years [kg CO2-Equiv.]		
Vehicle Production	7424,43	25,21%
Use Phase	21283,55	72,26%
End of life	747,32	2,54%
EP: Eutrophication Potential [kg Phosphate-Equiv.]		
Vehicle Production	2,75	27,23%
Use Phase	7,14	70,68%
End of life	0,21	2,10%
POCP: Photochemical Ozone Creation Potential [kg Ethene-Equiv.]		
Vehicle Production	3,14	31,17%
Use Phase	6,74	66,85%
End of life	0,20	1,98%

Table 5 : Environmental impact of the new ESPACE and repartition

For more information about the choice of indicators, refer to the methodological part (p 33).

As explained on the methodological part, we have chosen to give results for 2 recycling scenario. The following figure gives the results for scenario 2 (recycling credits are estimated and included in the recycling phase results).

Figure 3 : Repartition of environmental impacts of the new ESPACE along its life cycle, according to the recycling scenario with recycling credits

	QUANTITY	PART IN LIFE CYCLE
ADP fossil: Abiotic depletion Potential (fossil) [MJ]		
Vehicle Production	92303,30	25,01%
Use Phase	297227,34	80,54%
End of life	2387,30	0,65%
Recycling credits	-22859,72	-6,19%
AP: Acidification Potential [kg SO2-Equiv.]		
Vehicle Production	31,14	58,44%
Use Phase	28,90	54,24%
End of life	2,77	5,19%
Recycling credits	-9,52	-17,87%
GWP: Global Warming Potential 100 years [kg CO2-Equiv.]		
Vehicle Production	7424,43	26,77%
Use Phase	21283,55	76,73%
End of life	747,32	2,69%
Recycling credits	-1716,00	-6,19%
EP: Eutrophication Potential [kg Phosphate-Equiv.]		
Vehicle Production	2,75	28,54%
Use Phase	7,14	74,09%
End of life	0,21	2,20%
Recycling credits	-0,47	-4,82%
POCP: Photochemical Ozone Creation Potential [kg Ethene-Equiv.]		
Vehicle Production	3,14	33,07%
Use Phase	6,74	70,93%
End of life	0,20	2,10%
Recycling credits	-0,58	-6,11%

Table 6 : Environmental impact of the new ESPACE according the recycling scenario including recycling credits

III.2 COMPARISON BETWEEN ESPACE 4 AND ESPACE 5

The following figure shows the comparison between the Espace 4 & 5.

Figure 4 : Comparison between Espace 4 & Espace 5 for the selected impacts

The difference between Espace 4 and Espace 5 is comprised for each environmental impact between 16 and 38%.

The main difference for each impact concerns the production & the use phases; For the last one, the CO2 emissions decrease of 28% between the vehicles with the same level of performances.

III.3 RESULTS ANALYSIS

Before the results explanations, we can notice below some details about the cut-offs application:

Regarding the non-reassembled flows:

The table below shows that cutoffs on vehicle mass are lower than 1%.

Cut off criteria ESPACE		
	ESPACE 4	ESPACE 5
Total mass cut off (kg)	2,735	3,17
Cut off %	0,15%	0,19%

Regarding the spare parts:

For the moment, we don't take into account all the spare parts. We are thinking about a modification of our processes. Nevertheless, we can notice below the mass of spare parts regarding the vehicle mass. We have to keep in mind our goal which is making a comparison between 2 vehicles with the same hypothesis in term of spare parts used.

Maintenance			
	Espace 5	Espace 4	
x_lead	12,7	14,1	maintenance: qté de plomb de la batterie (kg)
x_acid	5,03	5,93	maintenance: qté d'acide de la batterie (kg)
x_brake_fluid	0,59	0,59	maintenance: qté de liquide de frein (kg)
x_cooling_fluid	5,77	5,77	maintenance: qté de liquide de refroidissement (kg)
x_glass_wash	24,08	24,08	maintenance: 4 x qté de liquide lave glace (kg)
x_lubricant	33,6	26,11	maintenance: 7 x qté d'huile (pour vidange) (kg)
x_tire	177,6	177,6	maintenance: 3 x masse totale des pneus (kg)
Masse totale	259,37	254,18	
Masse Vehicule	1636,15	1806,39	
% relatif de la maintenance	15,85%	14,07%	

Regarding the manufacturing scraps:

For the moment, we don't take into account the scraps coming from plants. As the spare parts, we are thinking about a modification of our processes.

Concerning the full LCA of cars, we can notice that the main contribution comes from the use phase.

The results analysis shows the details of the contributions of each phase of the vehicle life cycle.

Vehicle production:

The following figure shows the different contributors during the production phase of the vehicle.

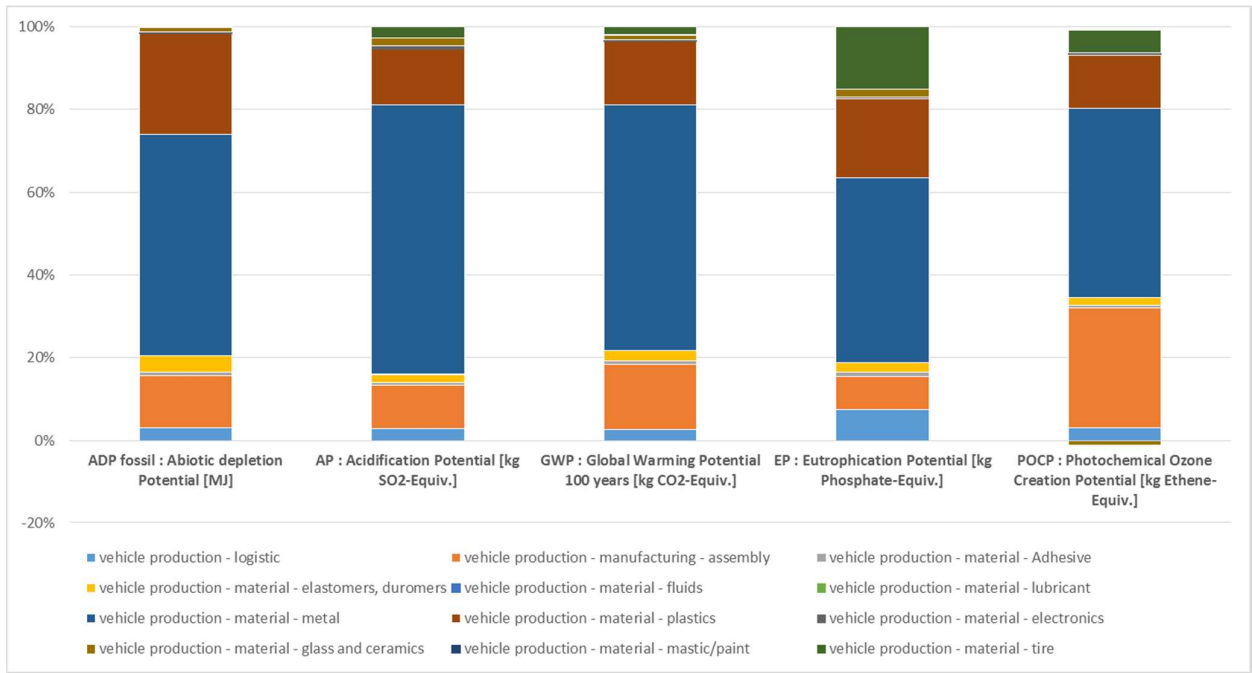

Figure 5 : Contributions for vehicle production

First of all, the contribution of materials is preponderant in the production phase. Logistics and manufacturing represent less than 10% of the impacts.

Within materials, metal and plastics are responsible for more than 80% of the impacts excepting for eutrophication in which the production of tire is significant. However, we notice that manufacturing is mainly impacted for POCP (around 30%) which representative the major impact of manufacturing.

Use phase Espace 5:

The following figure presents results for the different contributions of the use phase.

Figure 6 : Contributions for use phase Espace 5

For the use phase, contributions are closely linked to different indicators, but the production of fuel is really significant for all the impact (between 50% and up to more than 95% for ADP) excepting for the global warming

If we consider the driving phase of the vehicle (well to tank + tank to wheel), it represents more than 80% of the impacts except for eutrophication that also includes the maintenance of tires.

End of life Espace 5:

The following figure presents the contributions of end of life for each environmental impact.

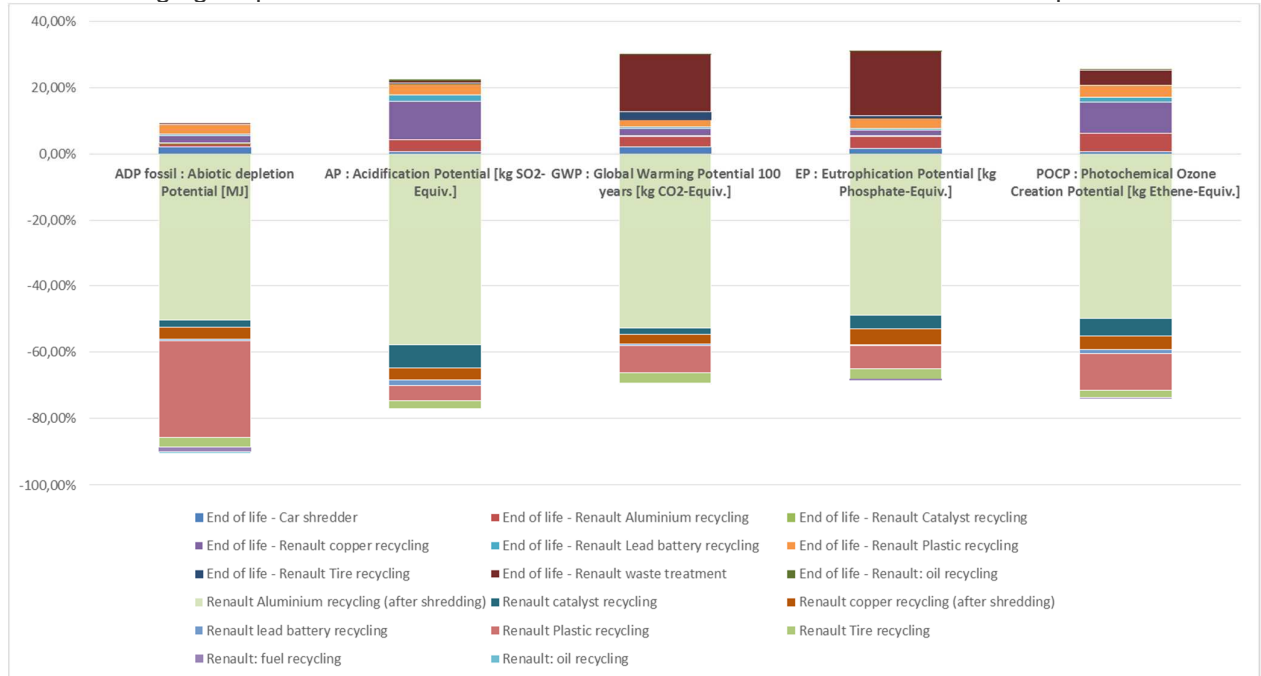

Figure 7: contributions for end of life Espace 5

Distribution of impact is specific for each type of recycling and associated credits. The main negative contributions are for copper recycling and waste treatment. These two contributors are responsible for more than 25% of the impacts for each impact. For recycling credits, the main benefits come from the aluminium, plastics recycling and catalyst recycling. Nevertheless its benefits, the process of plastics recycling is the third contributors in term of negative impact.

III.4 NORMALIZATION OF THE RESULTS

In order to give another interpretation of the results, it is possible to normalize the several potential impacts presented in this study. Normalization consists in dividing the value of the product per the value of a reference case on each indicator. This tool gives the contribution of the studied product on the chosen indicators. The normalization methodology is CML2001 Western Europe, which is in line with our scope. Normalization factors are available thanks to our GaBi software and Thinkstep database. They are gathered in the following table:

CML2001 - Apr. 2013, Western Europe (EU)		
Abiotic Depletion (ADP fossil)	3,06202 x 10 ¹³	MJ
Acidification Potential (AP)	27354100000	kg SO2-Equiv.
Global Warming Potential (GWP 100 years)	4,8832 x 10 ¹²	kg CO2-Equiv.
Eutrophication Potential (EP)	12821957276	kg Phosphate-Equiv.
Photochem. Ozone Creation Potential (POCP)	8241462011	kg Ethene-Equiv.

The results are presented below.

Figure 8 : Normalized results for Espace 4 & Espace 5

From this normalization, we can see that eutrophication burden and POCP are the lowest vehicle contribution for European emissions.

Concerning abiotic depletion potential, the vehicles' contribution comes from the large use of fossil resources for fuel production.

The figure highlights the large improvement between Espace 4 and Espace 5 on all environmental burdens but also the positive contribution of recycling mainly on the first three impacts.

IV CONCLUSIONS AND LIMITS

We performed in this report a comparison between Espace 4 and Espace 5 to identify the differences in term of environmental impact by using LCA.

We have defined 5 impacts to measure and compare our vehicles, and the analysis of each of them show us an improvement on Espace 5 compared to Espace 4.

We identify some significative improvements between the 2 cars. We can conclude based on the following hypothesis which allow to make the comparisons that ESPACE 5 has a lower environmental footprint than ESPACE 4:

- Same market and target in term of customers despite the design modifications.
- Same vehicle range.
- Same kind of engines and equipments.
- Same perimeters of comparison with the same use cases.
- ➔ Earnings are directly linked to the vehicle and due to its improvement in term of CO2 emissions, materials using, supply chain management.

However, we have to mention some limits for the vehicle study.

- Functionnal unit of 150000kms could be too short for a vehicle like Espace. We will think about new possibility to adapt the functional unit with the real use of the vehicle. This value could be more representative of the real use of the vehicle.

Vehicle range	Exemple	Functionnal unit (km)
Small	Twingo	100 000
Medium	Megane	150 000
Large	Talisman/Espace	200 000

The adaptative functional unit will be studied in 2016.

- The comparison with Espace 4 launched in 2002 shows a large improvement in term of environmental footprint, however, we have to keep in mind that the development of ESPACE 4 has been realized 20 years ago which can explain a part of the earnings. Nevertheless, the improvements are directly linked to the new ways of development.

In general for the LCA performance at Renault, we have identify some ways of improvement:

- We will sudy the possibility to include all the waste (manufacturing and maintenance which represents the main contribution to the global waste.).
- We have planned an updated of the oldest Databases with our supplier.
- We use for the moment only 5 impacts contrary to JRC. On this point, we won't make any modification.
- We don't take into account the contribution of the plants in term of building, but we are performing an update concerning the datas, and the values will be integrated in the future analysis.

We are continually improving our approach of the LCA analysis at Renault to include all the new developments and the remarks coming from experts of Solinnen.

B. RENAULT LCA METHODOLOGY

This part of the document presents the framework to conduct the Life Cycle Assessment studies of Renault vehicles.

This methodology is the same for all vehicle studies.

This methodology report is the version v1.

I INTRODUCTION / CONTEXT

Based on ISO 14040-44 standards, Life Cycle Assessment is a technique to assess in a scientific and objective way, all potential environmental impacts of a product, considering its whole life cycle: from cradle to grave as described in Figure 9.

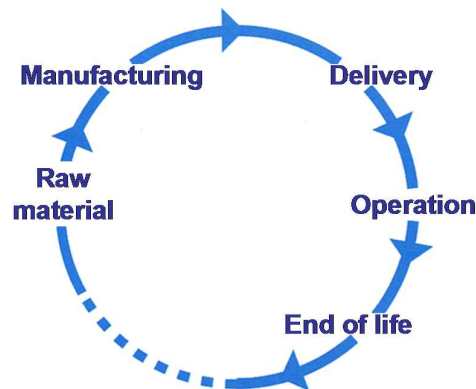

Figure 9 : Life cycle of a product

LCA studies comply with the ISO 14040 and 14044 standards [ISO 2006], and the following framework shows how to conduct LCA studies.

Generally Renault LCA studies compare the results for a vehicle launched with the predecessor vehicle.

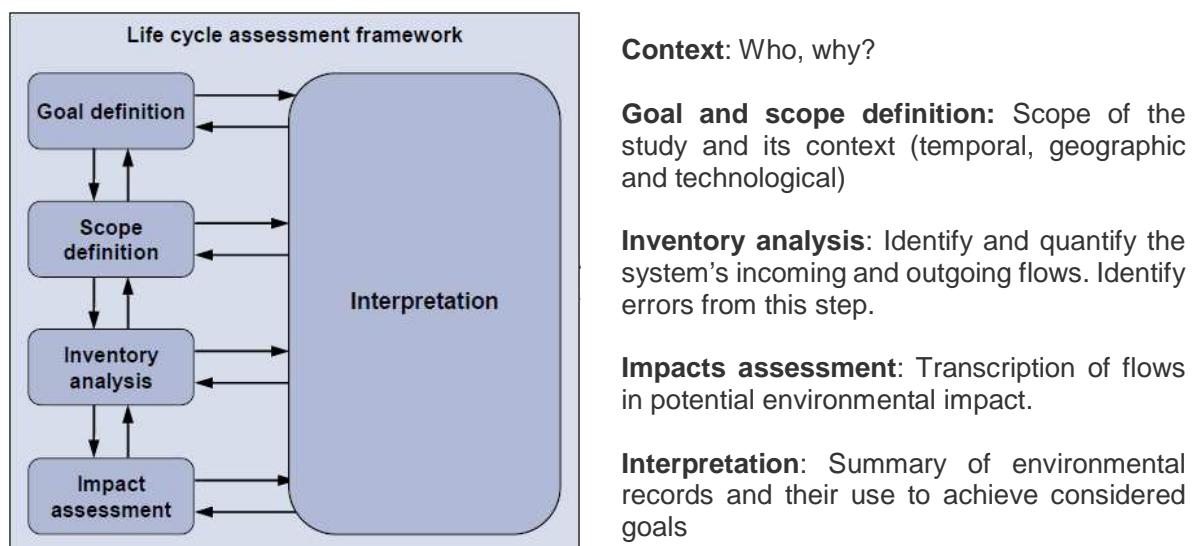

Figure 10 : Schematic table of LCA steps [EC 2010a]

II GOALS AND SCOPE OF RENAULT'S LCA STUDIES

II.1 GOALS OF RENAULT'S LCA STUDIES

The goal of Renault's LCA studies is to assess the environmental impacts of all new vehicles. When it exists, the goal of LCA studies is to compare the new vehicle with its predecessor.

The goal of the study is precisely detailed through six aspects:

- Intended application(s) and decision context
- Limitations
- Targeted audience
- Comparative studies to be disclosed to the public
- Commissioner of the study and other influential actors

II.1.1 INTENDED APPLICATIONS AND DECISION CONTEXT

LCA create new opportunities for the Group's strategy to diverse dialogues with stakeholders, thus improving the knowledge of the environmental impacts of Renault products. This methodology report describes the global framework and Life Cycle Inventory data sets to be used in Renault's calculation model. The methodology report is common for all vehicles studies. The life cycle is modelled by depicting the existing supply-chain attributionally. Primary physical data will be collected and associated to generic processes.

II.1.2 LIMITATIONS

An LCA study is an image of the product as it is launched and operates for defined time and mileage, as described in the functional unit (II.2.1).

A 10 year and 150 000 kilometers in the New European Driving Cycle (NEDC) standard is usually applied in Renault studies. It is a meanvalue and is not representative for all vehicles' use. However, Renault use this value in accordance with the compromise established between the CCFA and the automotive industry.

As a standard for all studies, benefits from the recycling processes, considered as potential credit, are not allocated to products. Results will be provided for information on the potential benefit for Renault.

Each LCA study is an attributional LCA and marginal or rebound effects are not taken into account.

Note: Limitations on new technologies (eg. Electric vehicle) are further detailed in relevant LCA reports.

II.1.3 TARGETED AUDIENCE

LCA studies are dedicated to the Renault internal audience and will be used as a reference by Renault management to define future environmental objectives for Renault products.

They will also provide a clear picture of the issues linked to specific parts production, and identify critical points to help engineers with ecodesign.

LCA studies will be available to expert stakeholders in order to sustain the dialogue on life cycle management and an executive summary can be prepared for non-expert readers.

An expert in environment and life cycle assessment will be assigned to review each report in compliance with the ISO 14040 standard and to validate the findings. The LCA critical review report is available with each LCA study.

II.1.4 VIGILANCE FOR PUBLIC DISCLOSURE

Studies are planned to be disclosed to the public.

It is not possible to make a direct comparison between the results of two different LCA studies, for instance from any other car manufacturer.

When a comparison is made it is described precisely in the specific vehicle study report and it usually concerns the comparison between the new vehicle and its predecessor.

The main objective is to maintain a logic when two vehicle are compared. We have to compare only 2 vehicles dedicated to the same market, with the same customer target and behavior. In the case of the new comer in the range, we will compare the new vehicle with the closest existed vehicle in the range. For example, we coul compare Kadjar and Short Scenic. They are dedicated to the same market, with the same objectives.

Thus it is also not possible to compare two different Renault vehicle studies (different model, technologies...).

II.2 GOAL & SCOPE OF THE VEHICLE STUDY

LCA reports detail and analyse the potential environmental impacts of different Renault models. The results are calculated in compliance with the ISO 14040:2006 and 14044:2006 standards. The detailed perimeter of LCA studies and data collection is presented below. All specific information concerning the vehicle with respect to scope definition is detailed in the vehicle dedicated LCA study.

The 2 studied vehicles are compared by using the same model. The methodologicals choices are the same and we use the same mapping file. The results are calculated by using the same database and also the same version. It allows us to make sure that the vehicles are compared with the same kind of inputs and the same updated methods.

II.2.1 FUNCTIONAL UNIT AND REFERENCE FLOW

- The functional unit defines and clarifies the qualitative and quantitative aspects of the function(s) along with some essential questions: “what”, “how much”, “how well”, and “for how long”.

Functional unit

- What: Transportation of passengers in a vehicle
- How much: 150 000 km (Europe geographic scope)
- How long: 10 years
- How well: Respect of the norms, studied vehicle type approval

Definition of a general vehicle functional unit:

Transportation of persons in a vehicle, for a total distance of 150 000 kms (~93 000 miles), during 10 years, in compliance with studied vehicle type approval norms (e.g. NEDC driving cycle)

- The vehicle itself defines the reference flow. It is described precisely in the chapter “Goal and scope of the vehicle study” of the dedicated LCA study.

II.2.2 SYSTEM BOUNDARIES

The LCA studies analyze all the necessary data to cover the 3 main steps that contribute to the life cycle impacts:

- the production of the vehicle which include materials extraction and parts production, logistic of parts and vehicle
- the use of the vehicle including also fuel production (Diesel, gasoline or electricity),
- the end of life treatment including dismantling and shredding

II.2.2.1 Cutoff criteria for initial inclusion of incoming (consumption) or outgoing (emissions)

A default cutoff criteria of 95% in mass or energy is applied on all study. In addition a criteria of 99% in mass is applied on the bill of materials of the studied vehicle and all substances of environmental significance such as toxic substances and rare resources shall be taken into account (as described in Figure 12). The cut-offs values are calculated for each vehicles as it is mentioned in part III.3.

NB: Omitted flows will not include toxic substances and rare resources like platinum or gold (i.e. electronic components)

- On the use of a thermal vehicle, for example with a consumption at 4L/100km, no more than 300 L can be neglected ($\approx 250\text{kg}$) (5% of a consumption of 4L/100km on a distance of 150 000 km during 10 years is 300 L)
- For various emissions (air, water, land) calculated flows are approximated to μg /reference flow.

For more information about cutoff criteria applied to the different elements of LCA software databases used: GaBi 6.0, report to documentation available at:

<http://database-documentation.gabi-software.com/>

Figure 12: Cutoff criteria representation

II.2.2.2 System modeling

The construction of infrastructures like trucks, roads or other buildings is excluded as they are the same for all vehicles studied.

Concerning factories, their impact is negligible and explained in the methodological report (V.1)

Figure 13 represents steps and elements constituting the system: perimeter included in the studies and the one which is excluded such as material second life benefits or vehicle sales.

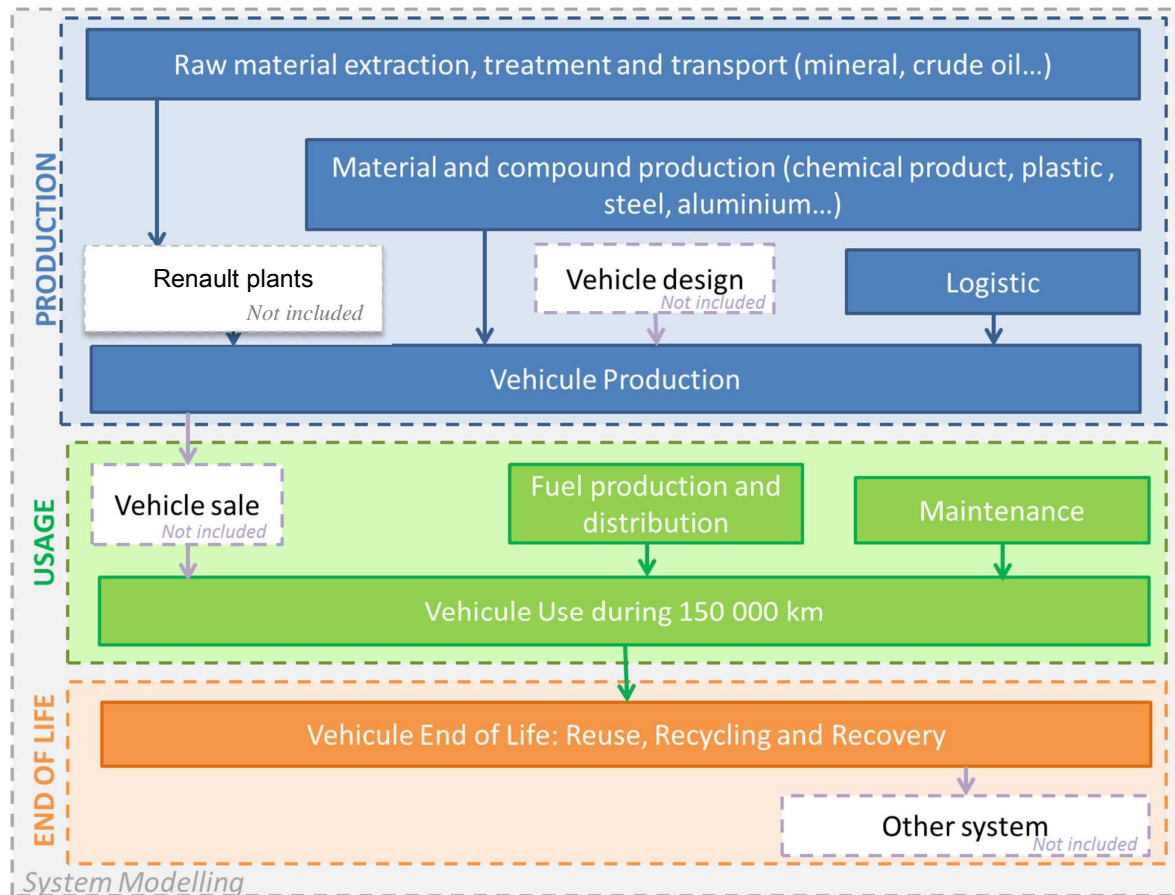

Figure 13 : Systems modeling

II.2.2.3 Production of parts and vehicles

The production phase gathers:

- The raw material extraction phase and also the production of the different Renault parts. These data are based on material information
- The assembly of the vehicle, thus including manufacturing inputs and outputs.

The identification of vehicles material content enables the estimation of the total supply chain impact from material production to processing stages.

The impact of transformation processes is proportional to the mass of material.

GaBi Thinkstep datasets are used to get the transformation impacts. It is average transformation information.

When choice is possible, the supply chain is modeled as European wide. In term of supply chain modelization, we don't take into account the supplier's localization. To apply a representative impact, we choose a value of 2000km as inbound impact by trucks. The list of all aggregated datasets used in the Renault modelling system is available in APPENDIX VI.4.

In the case of electric vehicles studies, the battery production is treated apart and specification is described in the relevant report.

II.2.2.4 Fuel production

Fuel production corresponds to the « well to tank (WTT) » step (whole production of fuel from extraction to vehicle's tank filling)

For Diesel, gasoline or electricity, Thinkstep GaBi datasets are considered depending on the country where the vehicle is sold (see APPENDIX VI.4).

II.2.2.5 Logistics

Logistic "inbound", which include all logistic of parts is estimated according to logistic experts in Renault. A sensitivity analysis shows that logistic inbound is not the main contribution of vehicle LCA results and that the estimation is relevant. We use a value of 2000km by trucks as inputs for logistic inbound calculation.

Logistic outbound, which include the delivery of assembled vehicles from the assembly plant to final customer is considered.

II.2.2.6 Use

The use phase, defined for 150 000 km, includes:

- Fuel consumption (gasoline, diesel, electricity)
- Atmospheric emissions from thermal engine operation and electricity production: CO₂, CO, NO_x, HC, SO₂, Particles PM10 (from diesel engines)
- Maintenance detailed in chapter III.5.3 :
 - Oil (drain), oil filters (thermal engines), tires, windscreen washer liquid, air conditioning

The hypothesis use for maintenance are the same for all the vehicles.

II.2.2.7 End of life

European Commission regulated the treatment of vehicles at their end of life.

Directive 2000/53/CE (through Decree n°2003-727) de fines following regulations for January 1, 2015:

- 85% of re-use and recycling
- 95% of re-use, recycling and recovery

The end of life modelling follows these regulations.

III LIFE CYCLE INVENTORY ASSESSMENT

III.1 DATA COLLECTION: METHODS AND PROCEDURES

The Data collection phase consists in gathering all information on any parts of the vehicle (material and process) but also on the manufacture and usage of the vehicle.

Once collected, this data is used in LCA software (GaBi 6.0), in a model developed by Renault, specifically dedicated to its needs. The life cycle pattern of the vehicle is the result obtained describing all processes and flows.

Collecting data to perform LCA is complex. It requires different information from all departments, not only technical data but also marketing data, environmental reports or material and parts details.

III.2 VEHICLE DESCRIPTION

For one specific Renault vehicle, there is a large variety of models that can be explained by:

- Different levels of equipment
- Different engines

The LCA is conducted for only one model (one level of equipment, but it is possible to conduct the LCA for one gasoline vehicle and also one Diesel vehicle).

This chosen model is the one that is concerned by the environmental Renault signature Eco2 (information on Eco 2 signature is available on Renault website).

The vehicle is also identified with a VIN number, required to obtain the homologation data, necessary to calculate the use phase.

III.3 VEHICLES' COMPOSITION

III.3.1 VEHICLE MATERIAL COMPOSITION

According to regulation (Directive 2000/53/EC of the European Parliament and the council on end of life vehicles and Directive 2005/64/EC of the European Parliament and the council on type approval of motor vehicles with regard to their reusability, recyclability and recoverability), Renault has to know for each vehicle sold the exact vehicle material composition.

To comply with these regulations Renault and other car manufacturers use IMDS (International Material Data System). This system gathers the information on material concerning every parts of the vehicle (from Original Equipment Manufacturers and their suppliers) so that Renault can have the material information for the whole vehicle.

Thanks to the IMDS material database, it is possible to describe the vehicle according different material categories. We use, if it is necessary to complete the IMDS datas, the same datas use for the recycling certification according to European regulation 2000/53/EC.

These data are those that are considered to get the whole impact of raw material during the vehicle life cycle thanks to GaBi software.

III.3.2 PROCESSING STEPS – PRODUCTION OF PARTS

As no information is available on each process (stamping, water consumption, energy consumption, emissions, etc...) specific to each part, Thinkstep developed datasets to describe the main material processes (stamping, Aluminium parts, plastic injection moulding...). These datasets are used and associated to the Renault's vehicle material description; The updated dates are mentioned in part VI.4.

In order to carry out the LCA calculation, the vehicle material and processing steps are described thanks to the BOM import fonctionnality which has been developed specifically for Renault's needs.

The GaBi datasets can be country specific. When the choice is possible, we prefer:

- 1- European datasets
- 2- Global dataset (world meanvalue)

- 3- If the choice is possible for different countries but there is no European or worldwide datasets, we choose preferably Germany which presents an interesting and representative electrical mix.

The list of all the datasets used in the vehicle model is available in APPENDIX VI.4. Bom import is a specific tool developed by Thinkstep for Renault. This software allows to define a relationship between the materials used in Renault's cars (coming from IMDS) and the specific flows defined in GaBi. The mapping uses for our LCA studies is already updated by the new analysis.

The figure mentions below as for goal to explain how our datas are collected.

Figure 14 : Bom Import

A mapping file links a set of processes (called Gabi plan) to each material or component. Therefore, each vehicle is fully modelled by its list of components and material (provided by the IMDS database via the BOM import software) and the associated plans (linked with the GaBi mapping tool).

III.4 FACTORIES AND LOGISTIC

III.4.1 LOGISTICS

Logistic is divided into inbound and outbound perimeters.

The logistic inbound is defined by all logistics of parts that are required for the assembly of vehicles.

These informations are difficult to gather and to allocate to only one vehicle (model and dedicated assembly plant).

Currently, in the LCA studies, we consider a mean distance value of 2000 km (by trucks) for inbound logistic. (This value is approximately estimated by the logistic expert. A study of sensitivity show that inbound logistic is not the main contributor for the whole vehicle LCA result.

Abiotic depletion (fossil) potential	Reference (Twingo 2): inbound according to logistic expert = 2000km)	100%
	Inbound / 2	-0,18%
	Inbound x 2	0,36%

Acidification potential	Reference (Twingo 2): inbound according to logistic expert = 2000km)	100%
	Inbound / 2	-0,43%
	Inbound x 2	0,85%
Global Warming potential	Reference (Twingo 2): inbound according to logistic expert = 2000km)	100%
	Inbound / 2	-0,16%
	Inbound x 2	0,32%
Eutrophication potential	Reference (Twingo 2): inbound according to logistic expert = 2000km)	100%
	Inbound / 2	-0,79%
	Inbound x 2	1,57%
Photochemical ozone creation potential	Reference (Twingo 2): inbound according to logistic expert = 2000km)	100%
	Inbound / 2	-0,17%
	Inbound x 2	0,35%

Table 7 : Sensitivity study for inbound logistic

The logistic outbound is defined by the delivery of the vehicle in retail network. These informations (number of km, transportation mode) are already and easily available and are used in LCA.

In order to explain our choice of a distance of 2000kms concerning the inbound and considering multiple hypothesis made to obtain and treat data from parts transport from first rank suppliers to the factory (assembly), it is important to verify if hypothesis were reasonable and if data was not over or under-estimated. So, we chose to modify distance of this transport to observe if it consequently changes our results. We doubled supply chain distance, from 2000 to 4000 km.

Following table gives results concerning impacts potentials (only global ones). We observe changes on vehicle production phase because supply chain is only part of this step.

Impacts potentials	Relative gap (petrol vehicle)	Relative gap (diesel vehicle)
Abiotic depletion (kgSb-eq)	+ 0.29%	+ 0.33%
Acidification (kgSO ₂ -eq)	+ 1.20%	+ 0.94%
Eutrophication (kgPO ₄ -eq)	+ 2.18%	+ 1.31%
Global warming (kgCO ₂ -eq)	+ 0.27%	+ 0.32%
Photochemical ozone creation (kgC ₂ H ₄ -eq)	+ 0.34%	+ 0.44%

Table 8: Comparison of environmental impacts following a modification of supply transport, applied on an average Renault vehicle

We observe a logical increase of all impacts from this mileage increase. The consequences of larger distances are larger fuel consumption and then pollutant emissions. But those increases do not overpass 5%, our cutoff criteria.

We can highlight the low contribution of supply transport on environmental impacts over the global life cycle and the negligibility of an approximation on this parameter.

III.4.2 FACTORIES

III.4.2.1 Impacts

Every plant participating in Renault vehicle production is ISO14001 certified.

Since 1998, Renault checks and controls consumptions and emissions to improve environmental performance. Since 2012, these data are mandatory standards in France (Article 225 of Grenelle 2 French law). We use these data to conduct the LCA studies. The advantage is that all information is available and updated each year. The detail of data is described just below:

- Energy consumption (electricity, thermal),
- Water consumption (industrial, domestic),
- Atmospheric emissions (CO, CO₂, CH₄, N₂O, NO_x, SO₂, VOC),
- Waste quantities (standard, specials)

These values are available in the annual Energy and Environment reports, they are updated each year.

III.4.2.2 Allocations

Renault sites are dedicated to the manufacture of different engines, gearboxes or vehicles. Impact allocation problems occur when a factory produces different engines and gearboxes, or when an assembly plant produces different cars. The contribution of each module needs to be estimated and calculated.

In our panel of plants, we could find assembly lines designed for vehicles, engines and gearboxes. In this case we have to identify the data from vehicle and from mechanical. Moreover, some factories produce different model on the same assembly line (vehicle or engines or gearboxes) and in this case the assumption is made that emissions are equally shared for vehicles that are assembled in the same factory. The same assumption is made concerning engine and gearbox.

All data necessary for the analysis and extracted from reports are gathered in tables' flows. These are available on the vehicle LCA study. These data are extracted from the scorecard and table report issued from the plants management.

III.5 USE

III.5.1 USE: FUEL AND ELECTRICITY PRODUCTION

Fuel production step starts with oil extraction or electricity production and ends at sale to customer. This step is named “well to tank”.

Data necessary to calculate this step are:

- Mileage done by the vehicle during its total use phase defined by the functional unit.
- Energy type (Diesel, gasoline or electricity) and its quality (sulfur rate, electric production mix...)
- Vehicle’s consumption, available on the homologation certificate

The environmental flows associated to these consumptions (incoming or outgoing) are included in the software.

In addition, we take into account the country where the vehicle is used. Indeed, the electrical mix is significantly different depending on country of use.

III.5.2 USE: CAR USE PHASE

Impacts of this phase are calculated from a mileage defined in the functional unit and according to the NEDC (New European Driving Cycle).

It requires the collection of the following data:

- CO, CO₂, HC, NO_x, SO₂ and particles PM10 emissions
- Fuel and electricity consumption

Tailpipe emission data and fuel or electricity production are included in conformity certificates (excluding SO₂ emissions).

Those certificates contain official vehicle type homologation data of Renault cars.

SO₂ emissions depend on sulfur rate of Diesel fuel. They are calculated with the following formula:

$$\text{ppm of S} * 2 * 10^{-6} * \text{consumption (en g/km)} = \dots \text{gSO}_2/\text{km}$$

With density:

Gasoline = 747g/l

Diesel = 835g/l

In 2012, all newly launched vehicles in Europe comply with Euro V tailpipe emission regulation: sulfur rate in gasoline and diesel is 10 ppm.

From its engine technology, an electric vehicle does not produce any tailpipe emissions like CO₂, NO_x, SO₂ or particles.

III.5.3 USE : MAINTENANCE

Maintenance operations (except crash) are described in Table 9

Operation	Life cycle frequency according to Renault recommendations (Thermal vehicle)	Life cycle frequency according to Renault recommendations (Electric Vehicle)
Air-conditioning fluid change	1	1
Pb-battery change	1	1
Brake fluid change	1	1
Cooling fluid change	1	1
Windscreen washing liquid change	4	4
Drain	7	0
Tire change	3	3

Table 9: Operation and frequency of maintenance operations

Concerning the wash of vehicles, as all washes are the same from one product to another, the water consumption is not considered to calculate impacts and then, not considered in Renault's studies.

III.6 END OF LIFE

The end of life scenario is based on End of Life Vehicles European directives (2000/53/CE and 2005/64/CE).

The recycling rate that has to be reached is 85% in term of recyclability and 95% in term of recoverability.

The recycling process follows the recommendation of the ISO 22628.

It takes into account the depollution phase, the dismantling of the parts and the shredding of the rest of the end of life vehicle.

Two different scenarios are modelled for the recycling phase:

- Scenario 1 – Reference scenario: we consider the processes for the dismantling and shredding of the end of life vehicle. Are also considered the recycling processes to produce secondary material, but recycling credits related to the production of the secondary material are not considered.
- Scenario 2: Recycling credits are estimated and included in the recycling phase results

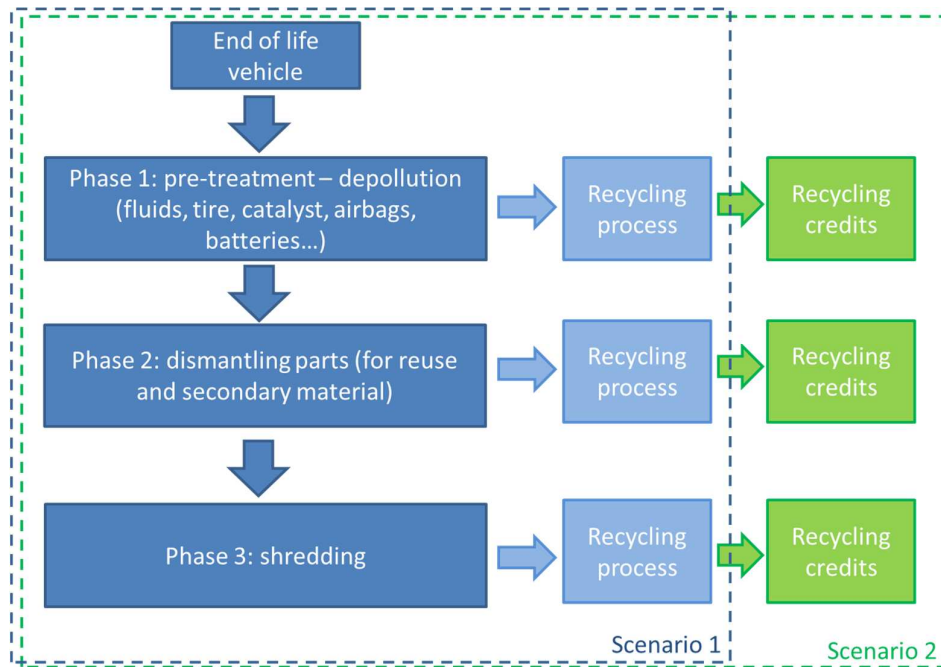

Figure 15 : Recycling modelling

Recycling Allocation:

Secondary material produced thanks to recycling processes can be considered as substitute for new material at production and consequently associated to a recycling credit.

Particular attention:

During the modelling phase of the production of the vehicle, data set used to model the production of raw material, provided by Thinkstep can take into account secondary material (For example, steel production takes into account the integration of secondary material). This secondary material must not be considered during the end of life process to avoid double counting.

III.7 QUALITY OF DATA

Process	Data specification			Data source

III.8 OVERVIEW OF ASSUMPTIONS AND DEFINITIONS FOR A LCA

The table below presents a summary of all the assumptions and definitions considered in a LCA study.

Intended applications

- Complete our range of LCA studies in order to compare each new vehicle with its predecessor or with a similar existed vehicle in the range.
- Set up new unit process and LCI data sets (eg battery) to be used in a new calculation model
- Build a comprehensive science based dialogue with expert stakeholders inside and outside of the company

Scope of assessment

- Function of systems:
Transport of passengers in a vehicle
- Functional unit:
Transportation of persons in a vehicle, for a distance of 150 000 kms (~93 000 miles), during 10 years, respecting vehicle type approval regulations (e.g. NEDC driving cycle)

Comparability

- Comparable performance figures
- Cars with standard equipment and fittings

System boundaries

- The system boundaries include the entire life cycle of the cars (manufacturing, service life and recycling phase), according to cut-off criteria.

Cut-off criteria

- The assessment includes maintenance but not repairs
- No environmental impact credits are awarded for secondary raw materials produced
- Cut-off criteria applied in GaBi data records, as described in the software documentation (www.gabi-software.com)
- Explicit cut-off criteria, such as mass or relevant emissions, are defined at 99% for the vehicle's definition and 95% for incoming flows.

Allocation

- Allocations used in GaBi data, as described in the software documentation (www.gabi-software.com)
- Allocations for end of life is described in the end of life chapter of the report

Data basis

- Renault vehicle parts lists
- Material and mass information from the Renault IMDS
- Emission limits (for regulated emissions) laid down in current EU legislation
- The data used comes from the GaBi database or collected in Renault plants, suppliers or industrial partners

Life Cycle Inventory results

- Life Cycle Inventory results include emissions of CO₂, CO, SO₂, NO_x, NMVOC, CH₄, as well as consumption of energy resources
- The impact assessment includes the environmental impact categories eutrophication potential, abiotic depletion potential, photochemical ozone creation potential, global warming potential for a reference period of 100 years and acidification potential
- Normalisation of the results to average impact per inhabitant values

Software

- Life Cycle Assessment software GaBi from Thinkstep, which release and update must be precised

Evaluation

- Evaluation of Life Cycle Inventory and impact assessment results, subdivided into life cycle phases and individual processes
- Comparisons of impact assessment results of the vehicles compared
- Interpretation of results

Table 12: Assumptions and definitions for the Life Cycle Assessment

IV LIFE CYCLE IMPACT ASSESSMENT

IV.1 INDICATORS CHOSEN FOR THE STUDIES

Environmental indicators were chosen in considering three criterias:

- Contributions known and supposed of automotive product.
- Diversity of ecosystems, local biodiversity, global resources depletion.
- Indicators positively considered by environmental experts and the European automotive industry.

The choice of indicators was validated by using the French matrix: adapted [ADEME 2011]

[ADEME 2011] Impact Assessment Proposals		EVALUATION			
		RELEVANCE	FEASABILITY	CONSISTENCY	FIABILITY
Global warming	✓	high	high	high	high
Abiotic depletion	✓	high	high	high	high
Water eutrophication	✓	medium	medium	medium	medium
Photochemical pollution	✓	medium	medium	medium	medium
Acidification	✓	medium	medium	medium	medium
Aquatic ecotoxicity	✗	medium	low	medium	low
Biodiversity	✗	low	low	medium	low
Land Use Change	✗	low	low	medium	low

Table 13: Impact assessment choice matrix

Concerning particles, even if they are a key topic for automotive industry, particularly for Diesel vehicles, they are not considered within an indicator. It is explained in the paragraph IV.12.

Characterization factors chosen are CML 2001 ones (More details at <http://www.leidenuniv.nl/cml/ssp/databases/cmlia/cmlia.zip>)

Figure 16: Impact categories chosen for the study

Indicators	Definition
Global Warming 100yr Potential (kg CO ₂ equivalent)	Quantifies non-natural increase of greenhouse effect gas concentration (CO ₂ , N ₂ O, CH ₄ , refrigerants...) in the atmosphere and consequently of global warming potential.
Acidification Potential (kg SO ₂ equivalent)	Characterize the acid substances increase (NO _x , SO ₂ ...) in lower atmosphere, source of acid rains and forests depletion.
Photochemical Ozone Creation Potential (kg Ethene equivalent)	Quantify the production of pollutant ozone (≠ to ozone layer), responsible of « ozone peaks », results of reaction of sunlight on NO _x and volatile organic compounds. This ozone is irritating for respiratory system.
Eutrophication Potential (kg Phosphates equivalent)	Characterize introduction of nutrient (nitrogenous or phosphate compounds per example) providing proliferation of algae, which consequence is the asphyxia of the aquatic world
Abiotic Resource Depletion Potential (fossil) (MJ)	Quantify non-renewable energies (crude oil, coal...) consumption leading to resources and abiotic depletion.

Table 14: Environmental impacts categories selected and definition

The environmental impacts determined in the Life Cycle Assessments are representing a specific burden to the environment; therefore, they are measured in different units. For instance, the global warming potential is measured in CO₂ equivalents and the acidification potential in SO₂ equivalents. In order to make them comparable, a normalisation process is required. In our Life Cycle Assessments, the results are normalised with reference to the annual average environmental impact caused by Western Europe.

Indicators	Impact caused by Western Europe inhabitants x 10 ⁻⁶
Abiotic Resource Depletion Potential (MJ)	30620200
Acidification Potential (kg SO ₂ equivalent)	27354
Global Warming 100yr Potential (kg CO ₂ equivalent)	4883200
Eutrophication Potential (kg Phosphates equivalent)	12822
Photochemical Ozone Creation Potential (kg Ethene equivalent)	8241

Table 15: EU 15 normalisation factors in accordance with CML 2001, Apr. 2013

IV.2 INDICATORS NOT CHOSEN

IV.2.1 HUMAN TOXICITY

It includes carcinogens and atmospheric pollution.

Concerning the automotive industry and particularly the use phase of the vehicle, toxicity potential impact is mainly coming from **particulate matters**.

These particles are fine dust from incomplete combustion. With a diameter inferior to 10µm, that can penetrate animal and human airway and cause asthma, inflammations or cancers.

PM 10 is only taken into account in human toxicity indicators.

In his research F. Querini [Querini, 2012] had studied the impact of different fuels on human toxicity (according to different methodologies). The results show that if Diesel fuel contribute to PM10 formation, the evolution of Euro standard have considerably reduce particles quantities and thus Diesel impact on toxicity.

On top of that, the LCA model takes into account only emission that follows Euro regulation and particulate matters are only measures since Euro 6 regulation. The consequence is that it is not possible to make a comparison between the wem vehicle and the replaced one.

When comparison will be possible particles and human toxicity indicator will be disclosed.

Focus on Carcinogens substances

Benzene is a substance contained in a low quantity (< 1%) in HC (unburned hydrocarbons emitted in exhaust gas), which carcinogen factor is recognised. However, there is not any limitation value, so it is difficult to evaluate its impact on human heath. In a prevention purpose, its concentration should be as low as possible.

IV.2.2 WATER CONSUMPTION

Water consumption integration in a LCA is a complex problem which methodology has been recently developed. (ISO 14046). We need to identify:

- Water used, treated and returned to natural environment (like washing water), from water consumed (demineralized water for paints)
- Process water used in multiple cycles, paying attention in considering it once.
- Water origin: groundwater cannot return there
- Geographic context: Water consumption importance is not the same in Europe or in Africa (*water scarcity* indicator needed)

Conscious of problems linked to water consumption and in an ISO 14001 approach, Renault works for reducing its use. In this way:

- Group's water consumption decreased of up to 55% from 1998 to 2010, associated to a 22,7% increase of the production
- Water consumption per vehicle produced decreased, from 11,3 m³/veh, to a small 4,14 m³/veh, representing a 63.3% decrease from 1998 to 2010.

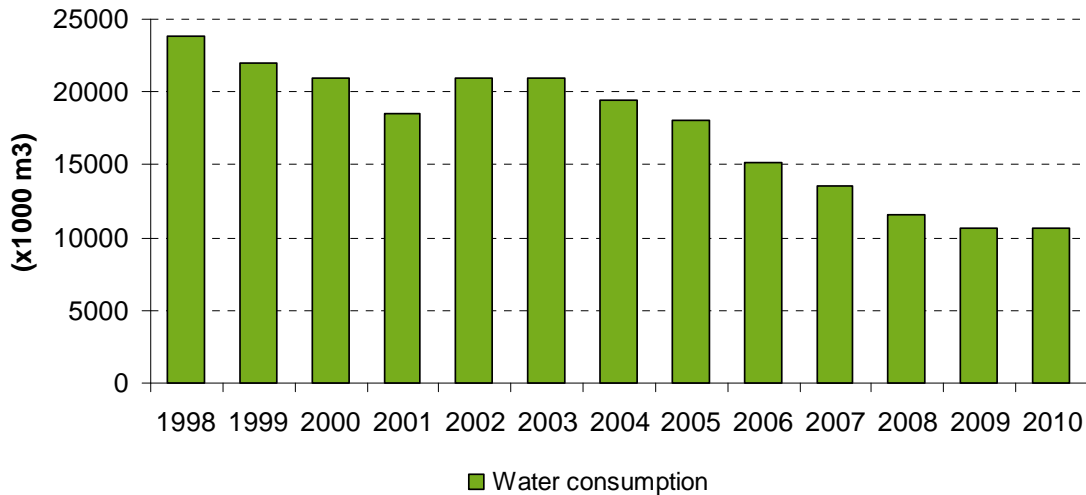

Figure 17: Water consumption reduction in Renault factories

From the ISO 14001 deployment in the group, Renault obtained a large amount of data about the different water sourcings. Water footprint integration will be the next step of the LCA deployment at Renault, as well as human toxicity. For the time being, Renault focuses on reducing the group's global water consumption.

IV.2.3 ROAD SAFETY

Although Renault dedicates a lot in this problematic, it is here out of the LCA context as it is a non-environmental issue.

IV.2.4 WASTE QUANTITY FROM THE SUPPLY CHAIN

Renault can control waste production provided on major steps of the vehicle production (assembly line, engine and gearbox production, Figure 18), but not all along supply chain (implication in an ISO 14001 approach or use of an eco indicator tool). For these processes and raw materials extraction, waste quantities come from software databases.

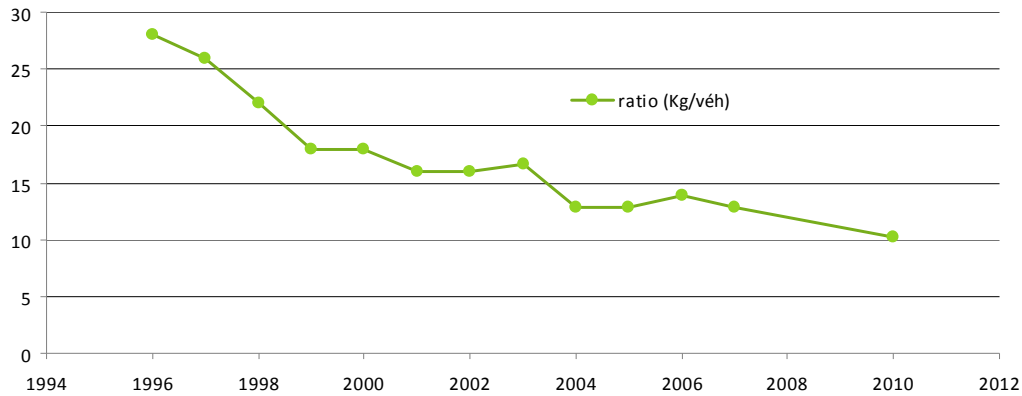

Figure 18: Evolution of packaging waste quantities at production. Quantity in kg per vehicle from 1996 to 2010

IV.2.5 NON-EXHAUST EMISSIONS

Non-exhaust emissions and especially particulate matter non-exhaust emissions are of course part of the emissions while driving. National emission inventories include copper in their scope and the transport sector is responsible for 87% of the total emissions. Road traffic accounts for a little bit more than a half of this amount (CITEPA SECTEN report April 2011). Some publications also address vegetation contaminations near road network.

Nevertheless, there are very few data, to be used as a recognized emission factor database, to achieve reliable calculations for those emissions. As there exists no regulation addressing this scope, industry performs tests to evaluate functional properties but those measurements do not allow evaluating lifetime wear emissions.

Another difficulty is linked to the various origins of those wear particulates:

- Brakes seem to be the main source of emissions. But the composition of the particulate matter is very much dependent on the technology; disc brakes are much more emissive than drum brakes.
- Due to the geometry of clutches, the particulate emissions are virtually zero.
- The tire debris.

In addition, the composition of those wear particulates depends very much on the supplier and some of those parts do not stand for the lifetime of the car and can be changed without any control of the supply chain by the manufacturer.

Taking only account about the copper emission factor coming from COPERT methodology would probably be as restrictive as not considering this source of emissions at all.

Any way, ignoring non-exhaust particulate matter probably leads to underestimate the absolute result of the life cycle impact analyses, but this is not a problem for a wide comparative approach, tires and break wear being included in all cars whatever there are EV or fossil fuelled.

V STANDARD HYPOTHESIS SENSITIVITIES

In order to ensure coherence of hypotheses performed and to measure the influence of some parameters, we performed a sensitivity analysis. We apply an important change to a parameter to check if the result is significant or negligible.

V.1 CONSIDERING FACTORIES?

V.1.1 FACTORIES MASS

We can consider that a factory (for example Tanger) is mainly made of concrete and steel. The main assumptions are:

- 40 kg of steel per meter square built;
- 500 kg of concrete per meter square built

With this assumption and since we have on the one hand the information of vehicles and engines produced for each plant, and on the other hand the estimated surface area for each plant, we can estimate the factory mass per unit produced (per vehicle or per engine).

The results are the following one:

47 kg of the factory for diesel vehicle

49 kg of the factory for gasoline vehicle

These values are quite negligible. Moreover, concrete represents 90% of the factory's mass and it is mainly constituted of aggregate (sand, pebbles). Quantity of energy necessary for its construction is low comparing to energy consumed by the system, and then negligible.

Considering now impacts, we show that the part of the factory allocated to each car is negligible on the global life cycle.

V.1.2 IMPACT CALCULATION

Data from concrete production environmental impacts comes from report <http://www.nrmca.org/sustainability/EPDPProgram/Downloads/NRMCA%20EPD%2010.08.2014.pdf> giving the impact of 1m³ of concrete composed of 80% of aggregate and needing 2187 MJ (0,94MJ per kg).

Production process of steel is based on GaBi database corresponding to European production, without considering an eventual recycling.

For logistics considerations, all of products are produced in Europe.

Quantities of energy consumed by machines to build the building are not included (cranes, diggers...). However, considering results bellow, in doubling environmental impacts values of the 50kg of the factory per vehicle, we are still under 1% for each impact on the global life cycle.

Then we can consider factories construction (and other infrastructures) as negligible on the global life cycle.

1,6l 16v (petrol)	Factory impact	System's impact on its life cycle (without considering factories mass)	Proportion on life cycle
Impacts potentials			
Abiotic depletion (kgSb-eq)	0.076	219.79	0.034%
Acidification (kgSO ₂ -eq)	0.12	60.10	0.20%
Eutrophication (kgPO ₄ -eq)	0.005	5.35	0.093%
Global warming (kgCO ₂ -eq)	16.4	34762	0.047%
Photochemical ozone creation (kgC ₂ H ₄ -eq)	0.01	12.44	0.080%

Table 16: Part of factory's construction a petrol vehicle's life cycle

1,5l dCi (diesel)	Factory impact	System's impact on its life cycle (without considering factories mass)	Proportion on life cycle
Impacts potentials			
Abiotic depletion (kgSb-eq)	0.073	169.55	0.043%
Acidification (kgSO ₂ -eq)	0.12	56.84	0.21%
Eutrophication (kgPO ₄ -eq)	0.004	6.92	0.057%
Global warming (kgCO ₂ -eq)	15.6	25463	0.061%
Photochemical ozone creation (kgC ₂ H ₄ -eq)	0.01	9.25	0.011%

Table 17: Part of factory's construction a diesel vehicle's life cycle

V.2 FACTORIES ALLOCATIONS

In order to justify established hypothesis or the need of amelioration of factories consumptions and emissions allocations (by the eco-risk tool), we increase values of those parameters by over 10% for all factories. Variations for diesel and petrol vehicles are gathered in the following table:

Impacts potentials	Relative gap (petrol vehicle)	Relative gap (diesel vehicle)
Abiotic depletion (kgSb-eq)	+ 0.04%	+ 0.20%
Acidification (kgSO ₂ -eq)	+ 0.18%	+ 0.39%
Eutrophication (kgPO ₄ -eq)	+ 0.19%	+ 0.28%
Global warming (kgCO ₂ -eq)	+ 0.15%	+ 0.33%
Photochemical ozone creation (kgC ₂ H ₄ -eq)	+ 0.44%	+ 0.61%

Table 18: Comparison of environmental impacts following a 10% increase of Renault factories' consumptions and emissions, applied on an average Renault vehicle

We note that none of impacts values reaches 0.7 on the global life cycle. It reveals the weak incidence of an allocation error of factories flows, which contribution stays under 1%.

REMARK: If part of the factories remains weak comparing to the global life cycle of a vehicle, any reduction of consumptions or emissions is beneficial.

V.3 HC ADDITIONAL SOURCE

V.3.1 PROBLEMATIC

The issue deals here with the potential evaporation of hydrocarbon vapors (petrol) during tank filling:

- From petrol delivery truck to petrol station
- From petrol station fuel pump to vehicle tank.

Because of petrol's volatility (not concerning diesel), part of hydrocarbons is emitted in the atmosphere bringing a potential increase of photochemical ozone creation. Moreover, presence of benzene (0.7% in petrol vapors) brings a public health problem because it is a carcinogen agent.

Current European legislation does not impose vapor recovery systems on those two steps (unless recovery systems are being developed). Automotive manufacturers ensure non-evaporation of petrol vapors once filler hose closed (canister system, tank's sealing)

Here is a sensitivity analysis when the gas station is equipped with a recovery system for vats filling. We only consider the impact on which the constructor can act.

REMARK: During petrol station vats filling, the emitted quantity allocated to each vehicle is the same than the one emitted during tank filling (same quantity of petrol consumed and same hypothesis concerning evaporation calculation. So we double variation of impact measured.

V.3.2 HYPOTHESES AND CALCULATIONS

For environmental impacts calculation, we consider hydrocarbon vapors to HC even if those are quite different (cf remark):

This pattern considers two hypotheses:

Liquid/vapor balance of petrol responds to Clausius-Clapeyron equation or pure, which form is: $\log P = A/T + B$

Petrol vapor responds to ideal gas law.

1) We consider averaged over the year the vapor tension of petrol to a median summer/winter value: 60kPa at 37.8°C (100°Fahrenheit)

Vapor tension is equally placed between Pentane and Hexane vapor tensions, which equations are:

$$\log P_{\text{pentane}} = -1458/T + 6.27$$

$$\log P_{\text{hexane}} = -1649/T + 6.83$$

with decimal log, P in kPa, T Kelvin, data from Handbook of Chemistry and Physics.

We consider petrol as a pure:

Average molar weight between pentane (72) and hexane (86): 79

Average coefficient between pentane and hexane: $\log P_{\text{petrol}} = -1550/T + B$; we calculate B with reference vapor tension : $\log P_{\text{petrol}} = -1550/T + 6.76$ (1)

With equation (1), we calculate vapor tension a different temperatures. At 20°C, $P_{\text{petrol}} = 30$ kPa.

2) We consider 1 liter of atmosphere saturated of petrol vapor at atmospheric pressure (101.3 kPa) and at 20°C (average temperature supposed).

Petrol partial pressure = 30 kPa

Total pressure = 101.3 kPa

In ideal gas approximation, total number of moles of gas = 1/22.4

Number of moles of petrol = (1/22.4) x (30/101.3)

Weight of petrol's weight

= (1/22.4) x (30/101.3) x 79 = 1.0 g of petrol vapor per liter of atmosphere in the tank.

Quantity of HC emitted during tank filling approaches 0.079 g/km for a vehicle consuming 7.9 liters/100 km.

At 20°C, this emission is very close to Euro IV emission regulation. If average tank temperature is 10°C, P_{petrol} becomes 19 kPa and emission approaches 0.052 g/km

V.3.3 RESULTS

Figure 44 represents evolution of photochemical ozone creation's impact during use phase, with a tank a 10°C and 20°C considering previous hypothesis.

Figure 19: Evolution of photochemical ozone creation potential, function of tank temperature (i.e. petrol vapors)

Impact potential	Reference (without evaporation)	At 10°C (HC = + 0,052 g/km)	At 20°C (HC = + 0,079 g/km)	Relative gap [10°C – 20°C]
Photochemical ozone (kgC ₂ H ₄ -eq.)	14.9	17.8	19.3	+ [19 - 29] %

Table 19: Value of photochemical ozone creation potential for use phase, function of tank temperature (i.e. petrol vapors)

Fuel vapors are very far from being negligible. There is a real need of vapors recovery.

However, this emission does not have the same geographic dispersion as exhaust gas.

Moreover, as stated previously, in many countries (England, United States...), recovery systems are compulsory and would be extended to rest of the Europe.

Currently in France, May 17th of 2001 order (<http://aida.ineris.fr/textes/arretes/text3272.htm>) relative to reduction of volatile organic compounds emissions due to petrol tank filling mandates recovery systems in gas station providing more than 3000 m³ per year. Moreover, any newly built gas station must be equipped with that system if it provides more than 500 m³ per year. A bill is currently studied to mandate those systems compulsory for any gas station. (<http://www.assemblee-nationale.fr/12/propositions/pion3471.asp>).

Then Renault does not consider these pollutant emissions in the vehicle life cycle.

However, this sensitivity analysis reveals the need of regulating it quickly on European perimeter.

VI.2 ABBREVIATION LIST

ADP: Abiotic depletion potential

AP: Acidification potential

CML 2001: name of the environmental impacts calculation method from the Institute of Environmental Sciences of Lieden Faculty of Science

ECU: Electronic control unit

ELV: End of life vehicle

EP: Eutrophication potential

EV: Electric vehicle

GWP: Global warning potential

ICE: Internal Combustion Engine

ISO: International Organization for Standardization

LCA: Life Cycle Assessment

LCI: Life Cycle Inventory

NEDC: New European Driving Cycle

POCP: Photochemical Ozone Creation Potential

Z.E.: "Zero Emission": commercial denomination of Renault electric vehicles.

VI.3 EUROPEAN EMISSIONS REGULATIONS

In mg/km

Diesel

REGULATION	EURO4	EURO5	EURO6
Nitrous Oxides (NOx)	250	180	80
Carbon monoxide (CO)	500	500	500
Hydrocarbons (HC)	-	-	-
HC+NOx	300	230	170
Particulates (PM)	25	5	5

Table 20: European emission standards for diesel engines

Petrol, LPG and NG

REGULATION	EURO4	EURO5	EURO6
Nitrous Oxides (NOx)	80	60	60
Carbon monoxide (CO)	1000	1000	1000
Hydrocarbons (HC)	100	100	100
Particulates (PM)	25	5	5
Non-methanous hydrocarbons	-	68	68

Table 21: European emission standards for petrol, LPG and NG engines

REMARK: For EV, as it is a zero emission from engine's operation, it fits all EURO regulations.

VI.4 LIST OF DATASETS FROM THINKSTEP USED IN RENAULT MODEL FOR TWINGO STUDY

For the TWINGO study, Renault vehicle model has runned with database 6.11 service pack 27. Some datasets are not up to date since they were used previously and have moved from Thinkstep availabled databases to paid extensions that Renault did not subscribed.
